

Hardware/Software, and Programming.

ROB PICKERING · 03 DECEMBER 2016 · SECURITY

The Internet of Things is a label that the computer industry, the media, and manufacturers have created to describe small devices that live on a network and

The Internet of things (stylised Internet of Things or IoT) is the internetworking of physical devices, vehicles (also referred to as "connected devices" and "smart devices"), buildings and other items—embedded with electronics, software, sensors, actuators, and network connectivity that enable these objects to collect and exchange data. [...] The IoT allows objects to be sensed and/or controlled remotely across existing network infrastructure, creating opportunities for more direct integration of the physical world into computer-based systems, and resulting in improved efficiency, accuracy and economic benefit. -- [Wikipedia](#)

In my household I've defined IoT to encompass the following types of devices:

- ▶ Any device with an IP address, not running a macOS, iOS, Android, Windows, or Linux operating system, that
- ▶ Does not require direct access to internal storage devices, and
- ▶ Does not store personal data

Examples of IoT devices in my home include:

- ▶ Philips Hue Lightbulbs and associated Bridge
- ▶ SmartThings Bridge
- ▶ Netgear Arlo Bridge
- ▶ Sonos Speakers
- ▶ Harmony Remote Hub
- ▶ Kindles
- ▶ Amazon Echos
- ▶ Ring Doorbells and Chimes

▶ II Video Cameras

- ▶ Any other types of WiFi connected sensors (Smoke detectors, Temperature, Humidity, etc.)
- ▶ Anything related to a **Smart Home** (lights, light switches, power, etc.)

Micro-Segmentation

What is micro-segmentation? This is a relatively new concept in security and is what I believe will be required in order to combat the threats we now face on the Internet and in our Enterprises.

Traditionally, if you were in Enterprise IT Security, you built a perimeter. The most common component of that perimeter was a Firewall. Things outside of the firewall were "bad", things inside the firewall were "good". The firewall protected us from the bad things by blocking them from coming into our network. You placed a firewall on your inbound Internet connection to keep yourself secure from everything running "out there". Next, you had to connect to a vendor, partner, or customer, so you extended your firewall to protect yourself from them as well. As your bandwidth to the Internet continued to increase, you eventually diversified and brought a connection into another site, which necessitated having another firewall, and a perimeter was born. It looks something like this:

The problem with Perimeter-style security is that you've made a fundamental assumption that things on the inside are "good" and things on the outside are "bad". This means that if something **does** get through the perimeter that all of a sudden it will be trusted to move around the inside network. That's a really bad assumption.

The perimeter defense also has another major flaw, you have to open it, a lot. Every time there is a service that needs to flow into or out of your network, you have to add firewall rules to allow it, this is also known as "opening ports". Since the firewall is your primary perimeter defense, that means you're "poking holes" in that defense (we actually use that phrase in IT, "poke a hole in the firewall"). Pretty soon your nice perimeter defense looks like this:

The more you poke holes in the firewall, the worse the perimeter defense looks. Every green arrow is an allowed connection into a network host, but then that host can connect to everything else inside.

Micro-segementation is an architecture that distributes the "perimeter" to only encapsulate, and protect, specific items (applications, services, servers, departments, etc.). Building this type of architecture will allow you to better protect each individual asset because you're only going to "poke holes" for the specific services required to run that asset.

I saw a great presentation on this from Edward Amoroso ([@hashtag_cyber](#)), which you can also read in this article: [Remove the balloon from the dartboard](#).

I believe that the larger threat globally is that our personal networks are not being adequately protected and yet they are growing at a **much** faster pace than Enterprise networks, with far less ability to secure them. We are all buying "Smart Things" at Home Depot and Lowe's and then bringing them home and plugging them into our personal networks. The same networks into which we plug our work laptops. For not a lot more money than a traditional, high-end, wireless network, you can instead build an architecture that protects yourself, but more importantly the World, from your Internet of Things.

To be honest, we aren't really going to be performing micro-segmentation. If we were going to do that, we'd have to take each of our IoT "hubs" (SmartThings, Philips Hue, Sonos, etc.) and segment each off to its own subnet (own network) with its own firewall rules. Micro-segmentation would be a great idea and would enhance the security of your network, but there are limitations to most prosumer (we're talking a level above standard consumer networks you buy at Best Buy or Staples, but a notch lower than most Enterprises) networking equipment that doesn't make it practical. Instead, we're going to segment our IoT devices into their own subnet, and SSID, to keep them segregated from our internal network.

The network equipment I decided to use was [Ubiquiti Wireless](#). I was first introduced to this equipment through a Security Researcher named Troy Hunt in his blog article titled [Ubiquiti all the Things](#). I purchased a similar set of equipment, but fewer Access Points (APs) as I had a smaller home to cover. My equipment list was the following:

- ▶ Ubiquiti USG [UniFi Security Gateway](#) (not the Pro Model)
- ▶ Ubiquiti UC-CK [Unifi Controller Cloud Key](#) (optional)
- ▶ 2 x Ubiquiti [Unifi US-16-150W PoE](#) Network Switch
- ▶ 1 x Ubiquiti [Unifi UAP-AC-PRO-US](#) 802.11ac Dual-Radio PRO Access Point

The total cost for all of this equipment was \$1,041.28 US. That's a lot of money for a network, but you could skip the Cloud Key (more later) and you probably won't need two switches (I did). I replaced the following equipment:

- ▶ Cisco SG 300-28 (28-port Switch) - \$492.89
- ▶ Cisco SG 300-10 (10-port Switch) - \$207.98
- ▶ Asus RT-AC3200 Tri-Band Wireless Gigabit Router - \$187.88
- ▶ Custom-built pfSense Firewall - \$374.99

Once everything was connected, the physical topology looked like this:

We'll be doing the segmentation with a combination of different [SSIDs](#) mapped to different [VLANs](#) being routed on different [Subnets](#). The beautiful thing about the Ubiquiti equipment is that the Ubiquiti Access Point (UAP) supports up to 4 different SSIDs, the switching equipment supports multiple VLANs, and the USG can route multiple IP subnets and provide DHCP service to each of them.

Initial Configuration

First, let me address the use of the Cloud Key. All of the equipment I'm discussing here is in Ubiquiti's UniFi line of networking equipment. All of these components are meant to be configured from a central management interface. You can still configure the equipment via console cables, or by SSHing into the system and using the Command Line Interface (CLI), but that's not the intent. The Cloud Key is an all-in-one device that provides the management interface for all of your Ubiquiti UniFi equipment. It is powered via Power-over-Ethernet (PoE) from the US-16 switch and makes the entire system turn-key. However, you can also run the Ubiquiti UniFi Controller for Macintosh, Windows, or Linux (you can even [run it in The Cloud](#)). This is a free download from Ubiquiti, but also means that you need to be able to have it

configuration.

The initial setup of the Ubiquiti equipment was straightforward, with the exception of the USG. The two US-16s were drop-in replacements for the Cisco switches and didn't require any initial configuration to start working. I then plugged the Cloud Key and the UAP into the first US-16 switch and they too just powered up via PoE from the switch.

When the Cloud Key came online, I connected to it at <https://unifi.ubnt.com/> which takes you to your Ubiquiti account and has a scanner that finds the Cloud Key on your local LAN. Once connected to your Cloud Key you set up an Administrator username and password and then "Adopt" each of your network components to be configured using the Cloud Key. This is where I ran into issues with the USG...

My internal network runs on an RFC-1918 subnet that is NOT 192.168.1.0/24. The DHCP service is being provided by my pfSense firewall and for the purposes of this upgrade I wanted to keep the pfSense firewall online during the migration, to minimize downtime. Unfortunately, the USG comes pre-configured to hand out 192.168.1.0/24 on the inside interface. In order to "Adopt" the USG into the Cloud Key, the Cloud Key **must** be able to talk to it on the same subnet. That means the Cloud Key **must** be on the 192.168.1.0/24 network, which was a real hassle in my configuration. I eventually had to bite the bullet and take the pfSense firewall offline, put the USG in, let everything pull 192.168.1.0/24 addresses, and then "Adopt" the USG into the configuration, before I could re-configure the USG to hand out the internal network I wanted to use...it burned several hours of my time, so hopefully you'll learn from reading this that you **must** put the USG into the network and just let it be the DHCP server and hand out the network it was configured to use, it'll add some time, but fighting it makes it worse.

The first step is to set up the VLANs you're going to be using for the various networks within your LAN. This is done through the UniFi Controller (Cloud Key) interface, found here:

CREATE NEW NETWORK

Name: **VLAN Name**

Purpose: ☒ Corporate ☐ Guest ☐ Voice ☐ VLAN Only ☐ Remote User VPN

Network Group BETA: ☒ LAN ☐ LAN2

IP/Subnet: **10.10.10.1/24**

Gateway IP: 10.10.10.1
Network Broadcast IP: 10.10.10.255
Network IP Count: 254
Network IP Range: 10.10.10.1 - 10.10.10.254
Network Subnet Mask: 255.255.255.0

VLAN: **10**

IGMP Snooping: ☐ Enable IGMP snooping

DHCP Server: ☒ **Enable DHCP server**

DHCP Range: **10.10.10.6** - **10.10.10.254**

DHCP Name Server: ☒ Auto ☐ Manual Name server 1 Name server 2

DHCP WINS Server: ☐ Enable DHCP WINS server WINS server 1 WINS server 2

DHCP Lease Time: **86400** seconds

DHCP Guarding: ☐ Enable DHCP guarding Trusted DHCP server

SAVE **CANCEL**

For the purposes of this discussion you should only need to create one additional network (for your IoT devices).

- Go to **Settings > Networks** and click **Create New Network**
- Configure a **VLAN Name**, set it as a **Corporate** network (this means it will have a separate subnet)

- ▶ After entering the CIDR (the /24) at the end of the gateway address, an **Update DHCP Range** button will show up, click this to automatically enable the DHCP Server and configure a DHCP range (adjust to suit)
- ▶ Enter a **VLAN** number (between 2-4095) for the IoT network
- ▶ Click **Save** when you're done with the configuration. You now have a VLAN in which your IoT devices can live.

UniFi 5.2.9

Wireless Networks

CREATE NEW WIRELESS NETWORK

Name/SSID: IoT Devices

Enabled: ☒ Enable this wireless network

Security: ☐ Open ☐ WEP ☒ WPA Personal ☐ WPA Enterprise

Security Key:

Guest Policy: ☐ Apply guest policies (captive portal, guest authentication, access)

ADVANCED OPTIONS ▾

VLAN: ☒ Use VLAN with VLAN ID 10

Hide SSID: ☐ Prevent this SSID from being broadcast

WPA Mode: WPA2 Only ▾ Encryption: AES/CCMP Only ▾

User Group: Default ▾

UAPSD: ☐ Enable Unscheduled Automatic Power Save Delivery

Scheduled: ☐ Enable WLAN schedule

802.11 RATE AND BEACON CONTROLS >

SAVE **CANCEL**

Next we need to create a new SSID and assign it to our new VLAN:

- ▶ Under **Settings > Wireless Networks**, click **Create New Wireless Network**

ROB PICKERING

HOME REVIEWS HOW TOS READING ABOUT CONTACT PGP

Under **Advanced Options**, check **USE VLAN** and enter your **VLAN** number

- You will now have an end-to-end solution for your IoT devices. Connect them to your new SSID, where they'll be mapped to your new VLAN, and routed directly to your USG and passed to the Internet

You now have your IoT devices on a separate network from your default LAN (which was the original network that the USG built for you, and to which you probably configured your initial SSID). Now when you add an IoT device to your network, configure it with your IoT SSID to provide segmentation. Additionally, you should also take any physically wired devices (SmartThings Hub, Hue Bridge, Sonos Bridge) and configure the ports in the switch to only speak on your IoT VLAN.

The screenshot shows the UniFi web interface. On the left, the 'DEVICE NAME' list includes 'UniFi Security Gateway', 'Computer Cabinet' (circled in red), 'Network Cabinet', and 'AccessPoint'. The 'Computer Cabinet' is selected, and its 'PROPERTIES' are shown. The 'CONNECTED' status is green. Below the properties, there is a grid of port status indicators. The 'Ports' tab is selected, and 'PORT 4' is configured. The 'Name' field is 'Port 4'. The 'PoE' section has 'Off' selected. The 'Networks/VLANs' dropdown is set to 'IoT (107)' (circled in red). The 'Details' and 'Configuration' tabs are visible at the bottom of the configuration panel.

APPLY

CANCEL

Perform the configuration for the Switch Port:

- ▶ Under **Settings** > **Clients**, select the appropriate switch
- ▶ Under the switch configuration, click **Ports**, then click the little **Pencil Icon** next to the port you wish to configure
- ▶ Change the VLAN assignment under **Networks/VLANs** to be the appropriate VLAN for your IoT devices
- ▶ Don't forget to **Apply** the changes, which will then provision those changes from your UniFi Controller to your switch

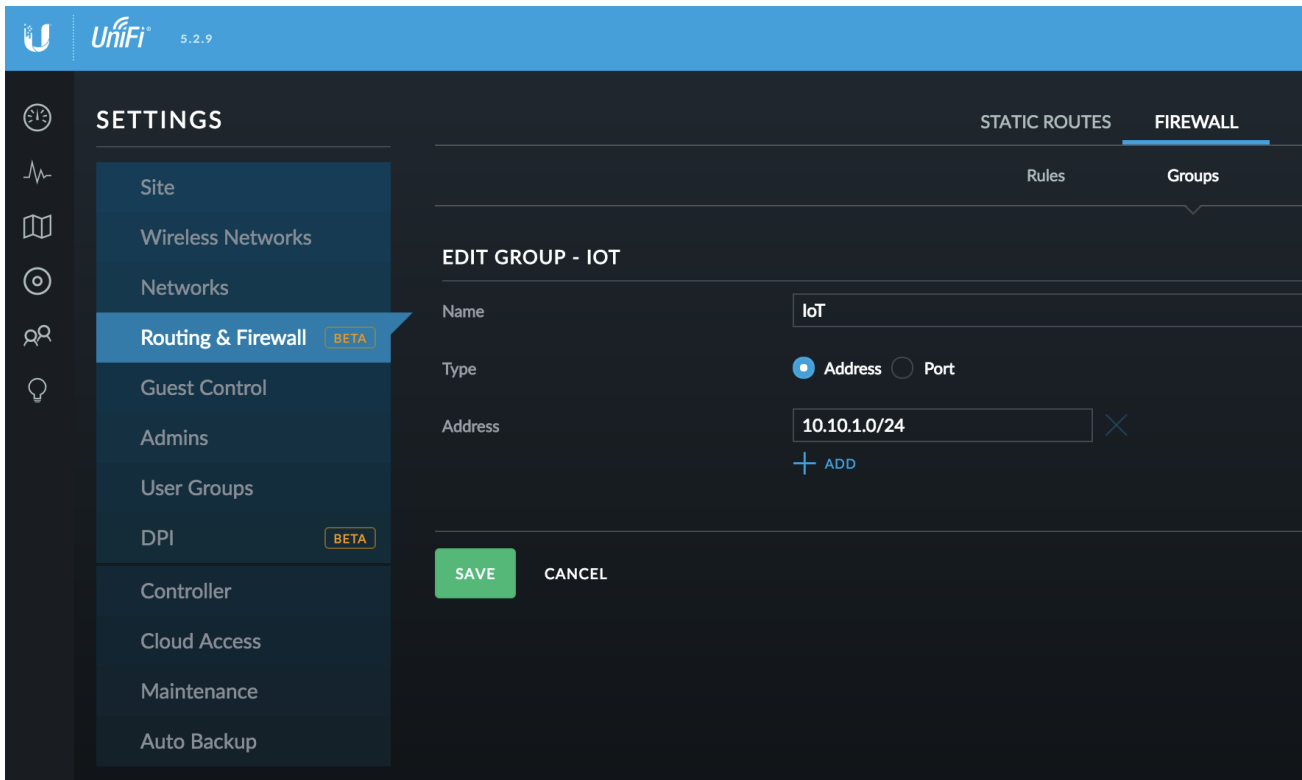

The network configuration is now complete. You should be able to have both wired and wireless clients join the IoT network and they should work normally. However, there is an additional security step you should take to complete the micro-segmentation of the IoT network.

Firewall the Things

The USG will automatically route all networks of type **Corporate** between each other (in fact, it creates uneditable/undeletable firewall rules to enable this behavior). You could have made your IoT network of type **Guest** which would allow you to automatically restrict its access to your Corporate networks, but in my case I set up my Guest network to have a Captive Portal. On the USG, all Guest networks have to be treated the same, so if one has a Captive Portal they all will and my IoT devices cannot authenticate via the web page, so they would be denied access. If, like me, you want to have a real Guest network, then you're going to have to firewall the IoT network from your Private network.

- ▶ **Private** (the primary, internal network for your computers)
- ▶ **Public** (the network that exists outside of your firewall, between you and your ISP, though you may not have one)
- ▶ **IoT** (the network you built for your IoT devices)

Groups are configured at your UniFi Controller:

- ▶ Access **Settings** > **Routing & Firewall** > **Firewall** tab
- ▶ Select the **Groups** tab
- ▶ Click **Create Group**
- ▶ Give the Group a **Name**, set **Type** to **Address**, and define the **Address** as the Subnet for that network

Firewall States

Before I jump into the configuration it will be important to understand something about firewall connection states.

The two most common states you encounter when working with firewall rules are:

- ▶ **New** - A brand new connection being opened to/from a remote site
- ▶ **Established** - An existing connection that has already been allowed through the firewall and subsequent traffic on that same connection is being allowed

Firewall Rule Configuration

At the Firewall we want to deny traffic from the Internet that is attempting to make a new connection into our network (**Unsolicited**), but we want to allow traffic from the Internet that is in Response to a connection that was Requested from inside the network (**Established**). You want to block bad guys from coming in, but you also want to see the web page from Amazon that you asked your web browser to open up when you typed in <https://www.amazon.com/>.

To block **New** connections coming from your **IoT** network into your **Private** network, configure a Firewall rule:

- ▶ Access **Settings** > **Routing & Firewall** > **Firewall** tab
- ▶ Select the **Rules** tab
- ▶ Click **Create New Rule**
- ▶ Enter a **Name** for the rule (e.g. DenyNewTrafficFromIoTtoPrivate)
- ▶ Select **before Predefined Rules** (or else it won't work)
- ▶ Select **Drop** as the **Action** (this is a Deny rule)

▶ **Enable logging** if you wish

- ▶ Check **New** for the **States** of the connections you will block
- ▶ Select **Address/Port Group** for both the **Source Type** and **Destination Type**
- ▶ Select your **IoT** group for the **Address/Port Group** under **Source**
- ▶ Select your **Private** group for the **Address/Port Group** under **Destination**

Once you click **Save** it will take approximately 60 seconds for the rule to be applied in your Firewall. If you only selected **New** under **States** then you should be able to still reach things in the **IoT** network from your **Private** network (e.g. ping them), but the reverse will not be true.

You can test your connectivity by placing an iPad or iPhone on the **IoT** network, then from the iOS device ping something on the **Private** network, it should be blocked, but when you ping the iOS device itself from the **Private** network, you should get a response.

If you desire complete segregation of the two networks, edit your Firewall Rule and check the other three states (**Established**, **Invalid**, **Related**) and save it. You will no longer be able to access systems across internal networks in either direction.

When testing you will ALWAYS be able to ping the default gateway (USG), even from the wrong network, since it is using sub-interfaces and you're really just pinging the same interface, so be sure to test actual hosts inside your various networks.

You now have a **MUCH** more secure network than when you started and you've successfully segmented your IoT devices from the rest of your network.

Please update this article with a revised controller version and firewall rules

7 ^ | ▾ 1 • Reply •

**amitp** • 2 years ago

Thank you! This was *very* helpful. Instead of moving an ssid over to a vlan which is tied to a firewall group, I used dhcp reservations to move the trusted devices to a firewall group. I'm guessing what I'm doing isn't as secure. Many of my IoT devices are on ethernet, and I don't have a Ubiquiti switch yet, so I wasn't able to assign devices to a vlan with port assignments. I will need to read more about vlans to understand what they can do for me.

3 ^ | ▾ • Reply •

**KW** • 2 years ago

How did you get your Phillips Hue to talk to your corporate network? I can only control the Hue / Lights if we are on the same SSID / VLAN.

2 ^ | ▾ • Reply •

**Pasha Davidson** > KW • 9 months ago

Did you ever get this working? I'm in the same boat

^ | ▾ • Reply •

**Rob Pickering** Mod > Pasha Davidson • 9 months ago

@Pasha Davidson and @KW I do in fact have my Hue bridge on my IoT network and use it just fine from my other network. I believe it requires mDNS enabled to allow this. Additionally, you have to have a rule (which is above) that allows your Private LAN to access your IoT LAN. If you don't then your Hue app won't be able to reach the bridge.
